

SENG1050

Lab 4

In this lab, you will gain experience in different forms of CSS.

[Task 1*](#) - [Task 2*](#) - [Task 3*](#) - [Task 4*](#) - [Task 5*](#)

Task 1 - Inline Style

Download this [HTML file](#) and open it in your editor.

For each list item below, set the font properties using inline CSS (the style attribute) so that the font reflects the text. You don't need to try every value for different properties. Try a few you like/want.

Once you've finished the task, open the file in two different browsers and compare the results side-by-side. What looks the same? What is different?

Font Style

- This text should be normal
- This text should be italic
- This text should be oblique

Font Weight

- This text should be normal
- This text should be bold
- This text should use 100 weight
- This text should use 400 weight
- This text should use 600 weight
- This text should use 900 weight
- This text should use lighter weight
- This text should use bolder weight

Font Variant

- This text should be normal
- This text should be in small-caps

Font Family

- This text should be in serif
- This text should be appear sans-serif
- This text should be in monospace

- This text should be in cursive
- This text should be in fantasy font

Absolute Font Size

- This text should be exactly 0.5cm
- This text should be exactly 24px. Note that px is relative to screen resolution, so this may look different on different size screens, such as mobile devices.
- This text should be exactly 2pc

Relative Font Size

- This text is the reference size for this section. Do not modify this text.
- This text should be smaller than the reference
- This text should be larger than the reference
- This text should be xx-small
- This text should be x-small
- This text should be small
- This text should be medium
- This text should be large
- This text should be x-large
- This text should be xx-large
- This text should be 50% of the reference size
- This text should be 100% of the reference size

- This text should be 300% of the reference size
- This text should be exactly 1.5em. The 'em' unit acts as a multiplier on the current font size, so 2em translates as: "2 times the size of the current font i.e. 200%. The 'em' unit tends to be more common than '%'. "

Task 2 - Embedded Document-Level Style Sheet

Open the page you created in Lab 2 (My Favourite Things - `index2.html`). If you can't find it, or didn't save it, you can use the provided `index2.html` on Canvas. Now that your web page has structure, you can add visual formatting suggestions using CSS.

1. In the content of the `<head>` tag, place a CSS `<style>` tag:

```
<style type="text/css">
</style>
```

2. Inside this `<style>` tag, add selectors for body and address tags:

```
body { }
address { }
```

3. Inside the braces ({ }) add some property-value pairs. For example, to make most text purple on a light blue background and aligned to the left of the page use `body { color: purple; background-color: lightblue; text-align: left }.`
4. To make text inside the address block forest green and aligned to the right of the page, use `address { color: forestgreen; text-align: right }.`
5. Reload the web page into your web browser to see the changes in visual formatting.
6. Add more style rules to change the formatting of level-1 and level-2 headings.
7. Add *pseudo-class* selectors for the email you have in `<address>` block. You should define pseudo-classes so that your email address appears differently when it is *unvisited*, *visited*, *hovered* and *selected*.

The page could look something like this.

My Favourite Things

BROMELIADS

I collect and grow these fascinating plants. My **obsession** started when I bought my first Bromeliad at the King Street Market a few years ago. I now have **over 30** of them, with the collection growing all the time. I now even give some away to friends when they grow new *pups*, which is the name of the new plants that grow from the old one.

- <http://bromeliad.org.au/>
- <http://bromeliad.org.au/DIARY/BXIII/064.jpg>

Bromeliads have fascinated gardeners and plant lovers since their introduction to the gardening world.

Computer Science

As with HTML, you should use a web validation service to check your CSS code. You can find a CSS validator [here](#). You can use the "validate by direct input" form and paste in the content of your `<style>` tag to be validated (not the style tag itself, just the contents).

Task 3 - External Style Sheet

External sheets are ideal for maintaining formatting consistency over many pages on a site. This task wants you to experiment with as many different styles as you can. See if you can implement the following styles, and watch their effect in the browser.

1. Create an external style sheet and link it in the HTML file using the `link` tag. The following tasks should be completed using the external style sheet.
2. Change the margin of the web page to 0px. Change it to 50px.
3. Change the type of bullets used for lists. Better yet, change the bullet to an image.
4. Add styles to insert a border around the image. Modify `margin`, `padding`, `border-width`, `border-style` and `border-color` properties.
5. Make all level-1 headings centre-aligned.
6. Insert a background image and repeat it throughout the page.
7. Set a background color (highlighting) behind all paragraphs. Try to set colour using both `rgb` and `hexadecimal` schemes.
8. Now use the same external style sheet to format both favourite pages you created in Lab 2 (`favourite01.html` and `favourite02.html`). Change some properties in your external style sheet and see how it is reflected in both favourite pages.

Task 4 - Formatting with CSS Selectors

Open the copy page you created in Lab 2 (My Favourite Things - `index2.html`). Now you will add visual formatting to this page using CSS selectors and watch their effect in the browser.

1. In the content of the `<head>` tag, place a `<style>` tag as you have done in [Task 2](#).
 2. Inside the `<style>` tag, add the following selectors:
 - One *ID* selector with `background-color` property. And use the `id` attribute in the target paragraph to receive the formatting.
 - One *class* selector with `color` property. And use that *class* name to format different tags in your `index2.html` file. For example one *paragraph* and one *list*.
 - Try to test one of the *descendant* and/or *sibling* selectors (Optional).
-

Task 5 - Cascading Multiple Style Declaration

In this task, you see how the styling rules defined at different levels are cascaded in CSS. Open the file you created in [Task 3](#) using external style sheet.

1. Insert a few document-level styles (inside the `head` element) to override the same styles defined in external style sheet with different values. For example define a different style for the bullets to override the style defined in the external style sheet.
 2. Check how the document-level styles override the external styles. If you swap the order of the `style` and `link` tags in the `head` element, notice how the cascade changes. Why does this occur?
 3. Now override the document-level styles you added in Step 1 using inline style declaration.
 4. Check how inline styles override the document-level styles.
-
